

## Lesson 6. Introduction to Dynamic Programming

### 1 The knapsack problem

**Example 1.** You are a thief deciding which precious metals to steal from a vault:

	Metal	Weight (kg)	Value
1	Gold	3	11
2	Silver	2	7
3	Platinum	4	12

You have a knapsack that can hold at most 8kg. If you decide to take a particular metal, you must take all of it. Which items should you take to maximize the value of your theft?

- This example problem is pretty small, so we can easily solve it by inspection

- Maximum total value:

- Items that give the maximum total value:

- We can also formulate this problem as a longest path problem:

- We consider filling up our knapsack in **stages**
- In stage  $t = 1, 2, 3$ , we decide whether to take metal  $t$
- The last stage (stage 4) represents the end of our decision process
- Node  $t_n$  represents

- The edges represent the **decisions** we can make
- Suppose we are deciding whether to take metal 2 (silver), and we have 5 kgs of space left in our knapsack
- Two possible decisions:

1. Take metal 2

◦ This is represented by the edge

◦ This decision has a value of

, so we use this as the length of this edge

2. Don't take metal 2

◦ This is represented by the edge

◦ This decision has a value of

, so we use this as the length of this edge

- We can complete the rest of the digraph in a similar fashion
- **Key observation.** Finding an optimal solution to the knapsack problem is equivalent to finding the longest path in this graph from node  $1_8$  to some stage 4 node
  - In this example, the longest path is  $1_8 \rightarrow 2_5 \rightarrow 3_5 \rightarrow 4_1$  with a length of 23
  - The longest path length tells us:

◦ The nodes and edges in the longest path tell us:

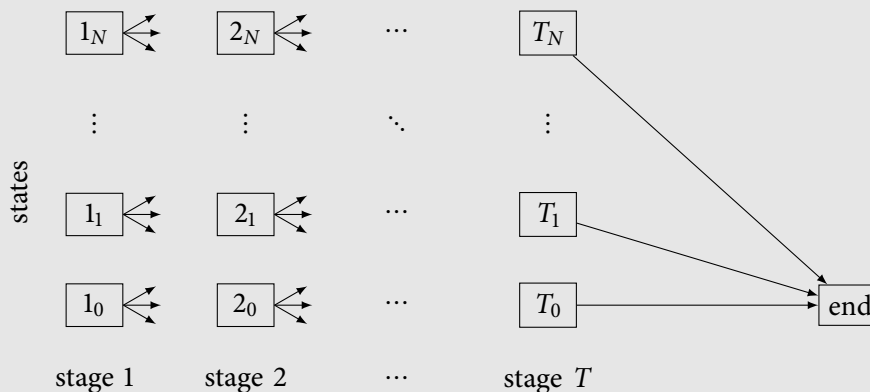

- To reformulate this as a shortest path problem:
  - Negate all edge lengths
  - Connect all stage 4 nodes to an “end” node with edges of length 0
  - Find the shortest path from node  $1_8$  to the finish node

## 2 Dynamic programming

- A **dynamic program** (DP) is a mathematical model that captures situations where decisions are made sequentially in order to optimize some objective
- In particular:
  - DPs divide problems into **stages** with a **decision** required at each stage
  - Each stage has a number of **states** – the possible conditions of the system at that stage
  - A decision at each stage transforms the current state into a state in the next stage with some associated **cost** or **reward**
- DPs come in several different flavors, and can be described in various ways
- For now, we will think of a DP as a specially-structured shortest/longest path problem

### Dynamic program – shortest/longest path representation

- **Stages**  $t = 1, 2, \dots, T$  and **states**  $n = 0, 1, 2, \dots, N$
- Directed graph:

- Node  $t_n \leftrightarrow$  being in state  $n$  at stage  $t$ 
  - ◊ Nodes for the  $t$ th stage are put in the  $t$ th column
- Edge  $(t_n, (t+1)_m) \leftrightarrow$  the **decision** to go to state  $m$  from state  $n$  at stage  $t$ 
  - ◊ Length of this edge = **cost** or **reward** of making this decision
  - ◊ An edge must connect a node in the  $t$ th column to a node in the  $(t+1)$ st column
- Nodes for the last stage are connected to an “end” node
  - ◊ Typically: all nodes in last stage are connected to the end node with edge lengths of 0
- Shortest/longest path problem:
  - Source node = one of the first stage nodes (depends on the problem)
  - Target node = end node
  - Edge lengths correspond to rewards  $\implies$  Find the longest path from source to target
  - Edge lengths correspond to costs  $\implies$  Find the shortest path from source to target

**Example 2.** The Simplexville Police Department wants to determine how to assign patrol cars to each precinct in Simplexville. Each precinct can be assigned 0, 1, or 2 patrol cars. The number of crimes in each precinct depends on the number of patrol cars assigned to each precinct:

Precinct	Number of patrol cars assigned to precinct		
	0	1	2
1	14	10	7
2	25	19	16
3	20	14	11

The department has 5 patrol cars. The department's goal is to minimize the total number of crimes across all 3 precincts. Formulate this problem as a dynamic program by giving its shortest/longest path representation.
