**Start with Problem 2 on the reverse side.**

**Problem 1.** Solving for the value-to-go function  $f_t(n)$  and the optimal decisions  $x_t^*$  of the stochastic dynamic program defined in Problem 2, we obtain:

$t$	$n$	$f_t(n)$	$x_t^*$	$t$	$n$	$f_t(n)$	$x_t^*$
1	0	0	0	3	0	0	0
1	1	47200	1	3	1	120000	1
1	2	135800	1	3	2	250000	0
2	0	0	0	4	0	0	-
2	1	68000	1	4	1	250000	-
2	2	187500	2	4	2	250000	-

a. Based on the table above, what is the company's minimum total expected cost?

b. Based on the table above, if the company still needs 2 microchips by the time it reaches its 3rd production run, what should the company do?

**Problem 2.** Strogatz Semiconductors has received an order to supply 2 custom microchips. These custom chips are difficult to produce, and the company may have to manufacture more than one chip to obtain one that is acceptable. The company has time to make no more than 3 production runs, and at most 2 chips can be produced in each run. The probability of having a certain number of acceptable chips in a given run depends on how many chips are produced:

Number of chips produced	Probability of acceptable chips		
	0	1	2
0	1	0	0
1	0.40	0.60	0
2	0.35	0.50	0.15

Each chip costs \$20,000 to produce, and excess chips are worthless. If 2 acceptable chips have not been obtained by the end of the third production run, the company is in breach of contract and must pay a penalty of \$250,000.

The objective is to determine how many chips to produce in each production run in order to minimize the total expected cost. Here is the start of a stochastic dynamic program that models this problem:

- Stages:

$$\begin{aligned}
 t = 1, 2, 3 &\leftrightarrow \text{production run } t \\
 t = 4 &\leftrightarrow \text{end of process}
 \end{aligned}$$

- States:

$$n = \text{number of acceptable chips still needed} \quad \text{for } n = 0, 1, 2$$

- Allowable decisions  $x_t$  at stage  $t$  and state  $n$ :

$$x_t \in \{0, 1, 2\} \leftrightarrow \text{number of chips to produce in production run } t \quad \text{for } t = 1, 2, 3; n = 0, 1, 2$$

- Value-to-go function:

$$\begin{aligned}
 f_t(n) = \text{minimum total expected cost for production runs } t, \dots, 3 \\
 \text{with } n \text{ acceptable chips still needed}
 \end{aligned}
 \quad \text{for } t = 1, 2, 3, 4; n = 0, 1, 2$$

Specify the transition probabilities and contributions from state  $n = 2$  at stage  $t$  ( $t = 1, 2, 3$ ) on the diagram below:
