Problem 1. Simplex Pizza sells New York style and Sicilian style pizza by the slice. Let N represent the number of New York style slices in one order, and let T represent the total number of slices in one order. The joint probabilities of N and T are as follows:

		T		
		1	2	3
N	0	0.10	0.05	0.01
	1	0.25	0.10	0.02
	2	0	0.35	0.04
	3	0	0	0.08

- What is the probability that an order contains a total of 2 slices?
- What is the probability that an order contains 2 New York style slices, given that the order contains a total of 2 slices?

Problem 2. The Orange Company was having problems with its automated manufacturing cells yesterday: sometimes a tablet came out of a cell defective. 65% of the tablets were produced in cell 1, 25% in cell 2, and 10% in cell 3. 1% of the tablets produced in cell 1 came out defective, 1% in cell 2, and 5% in cell 3.

Suppose you select 1 tablet made yesterday at random. Let C be a random variable that represents the cell it was produced in (i.e., $C = 1, 2$ or 3). In addition, let D represent a random variable indicating whether the tablet came out defective (i.e., $D = 1$ if defective, 0 otherwise).

a. What is the probability that the randomly selected tablet came out defective, i.e. $\Pr\{D = 1\}$?

b. Are C and D independent? Give a numerical argument for why or why not.
